Soundings used in SRTM15/30_PLUS

multibeam, singlebeam, grids, . . .

1/2 of global seafloor bathymetry not resolved at 10 km resolution

areas of seafloor more than 10 km from a sounding

Data available at GEBCO Data Store

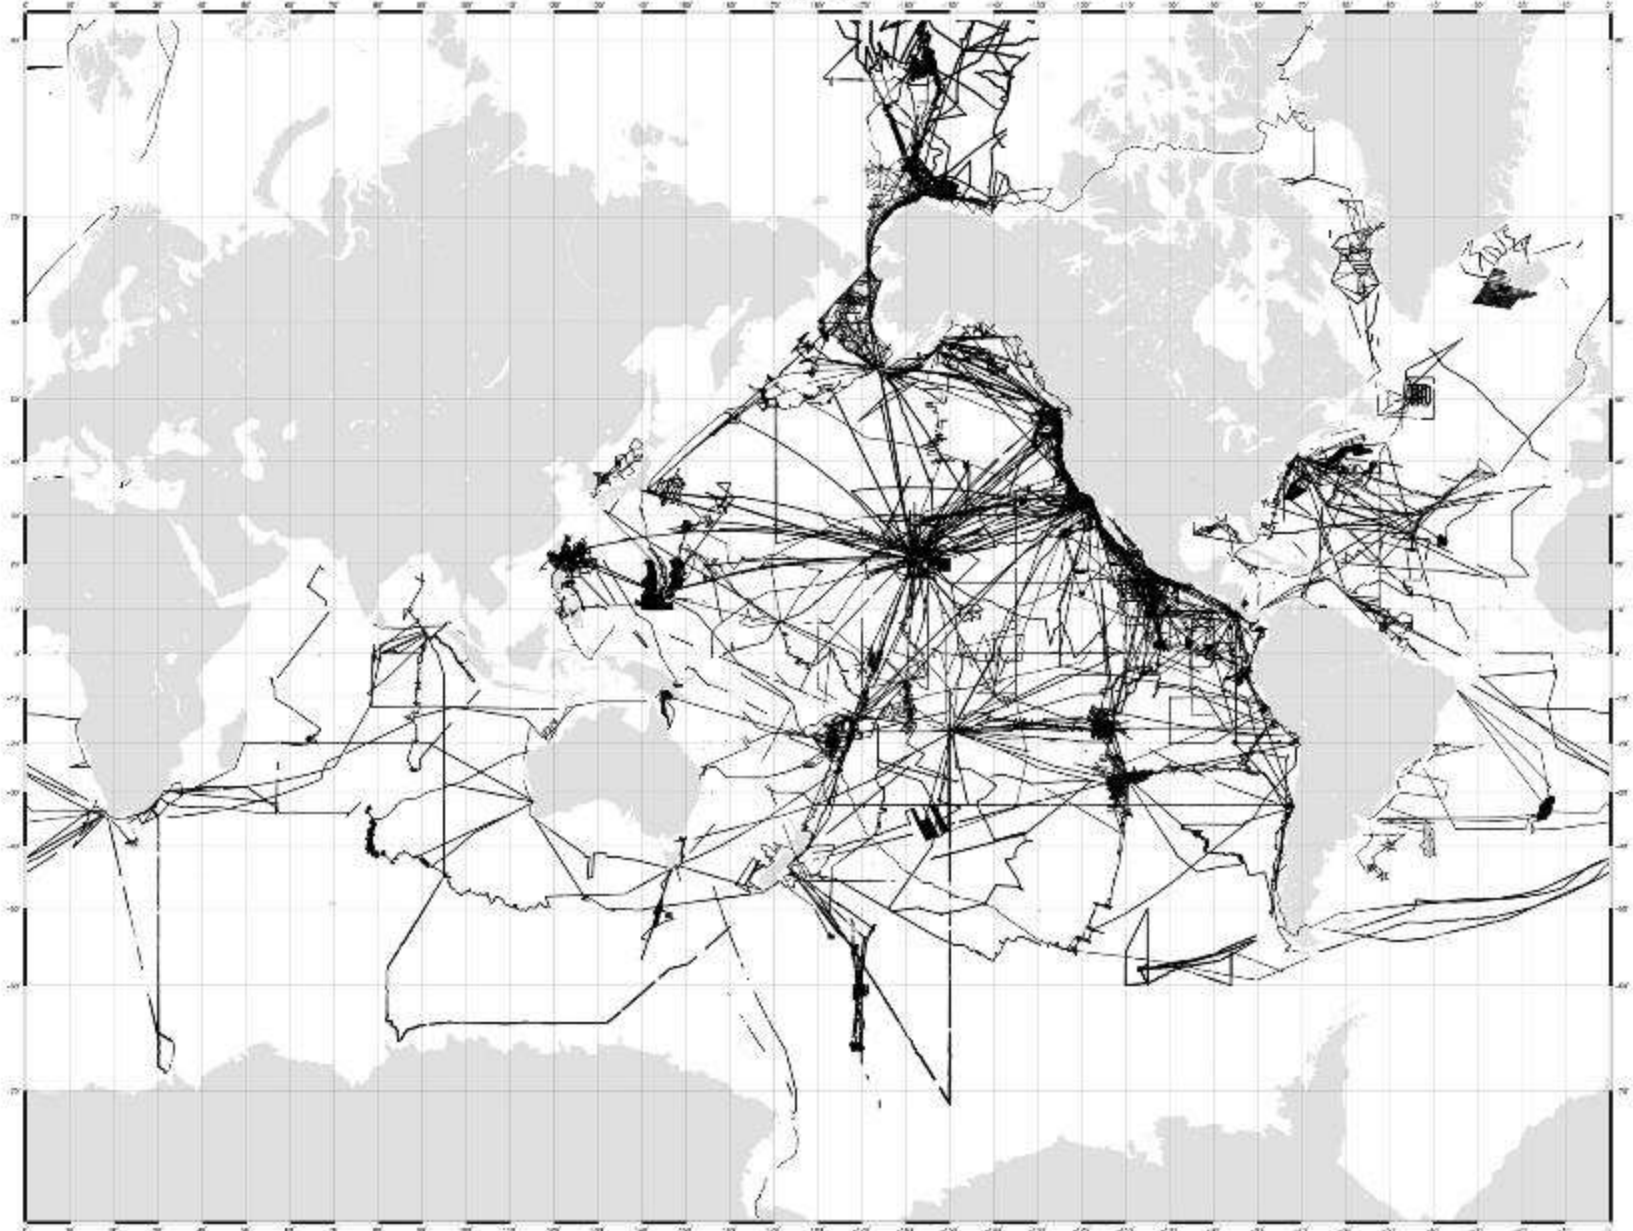

- Soundings blockmedian at 500 m spatial resolution
- Common cm-format – 9317 files – 439 million soundings
- Bad soundings flagged
- Source Identification Number (SID) used to link soundings back to original source

Two editing approaches

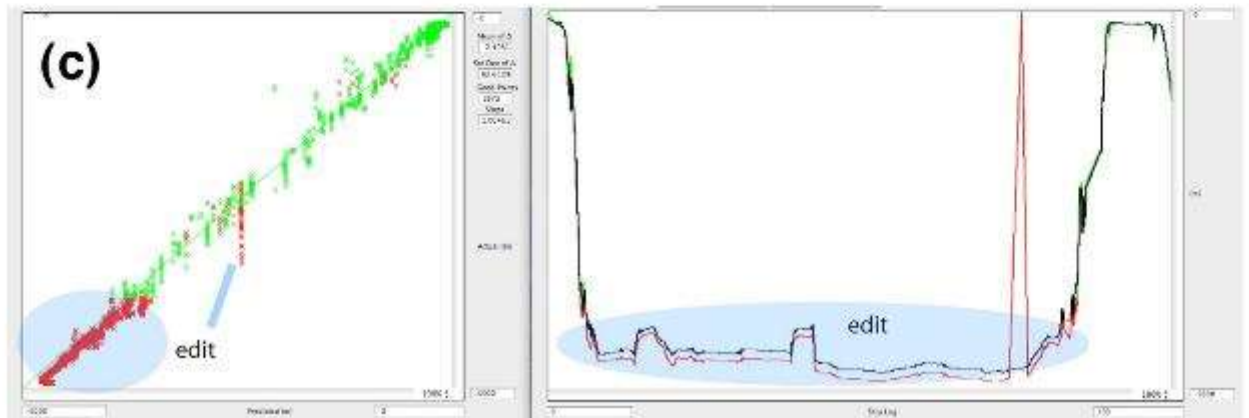

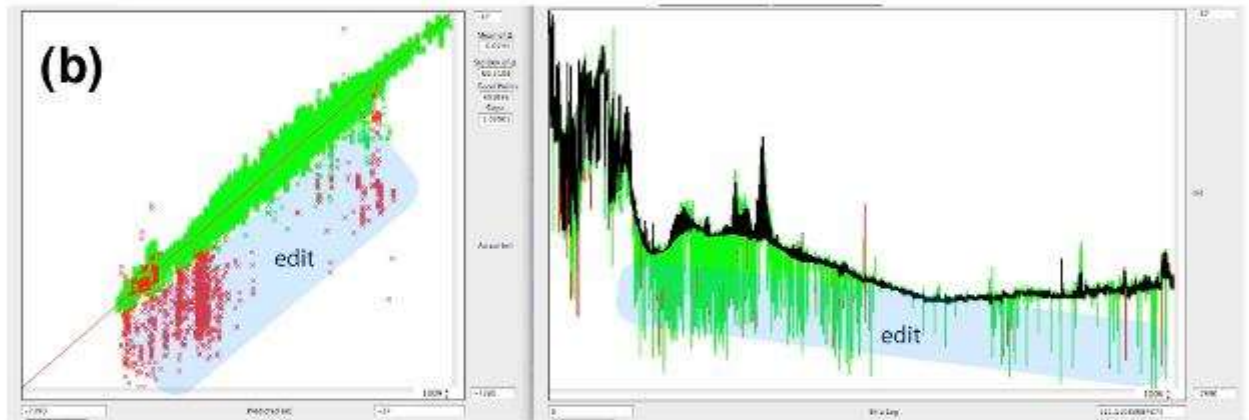

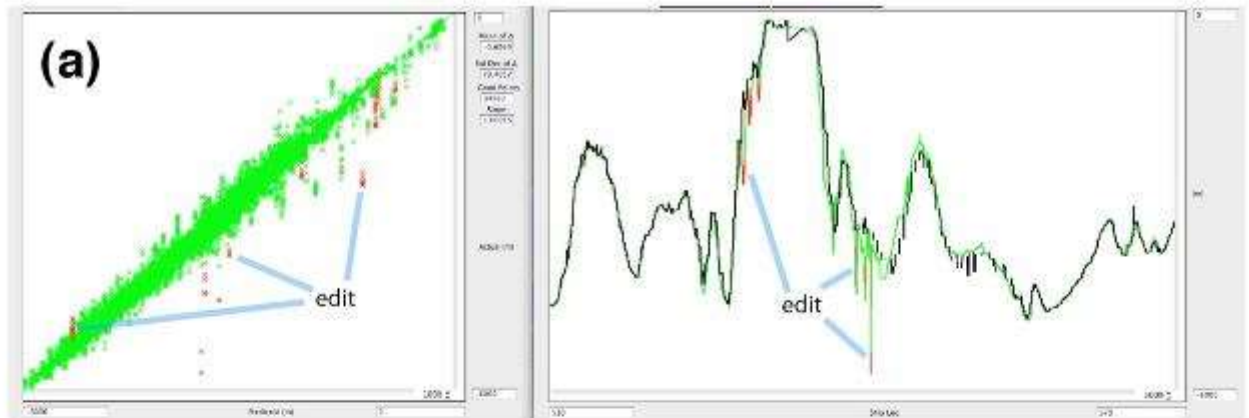

1. Compare single cruise file with predicted depth. Good initial screening of every new file. Easy to spot blunders. Time consuming.
2. Look for blunders and ugly points in Google Earth guided by global gravity. Draw polygon around bad data. Use SID grid to identify cruise file(s). Flag data inside polygon(s). Time consuming.

Iterate on 1 and 2.

CM editor

Becker et al., 2009

Three examples of editing files of sounding data using a program *cmEdit*. The three windows on the left show the **statistics** window where measured depth is compared with predicted depth and the misfit statistics are displayed. The three windows on the right show the **data** window where measured depth (green) and predicted depth (black) are plotted together. The analyst highlights bad soundings (red) and the flagged data are not used in the next version of the global bathymetry grid. **(a)** Example from a single-beam cruise having a few outliers. **(b)** Example from a multibeam cruise having numerous outliers. **(c)** Example from a single-beam cruise where the deep-ocean data have a bias perhaps due to an incorrect sound velocity correction.

How can we do better?

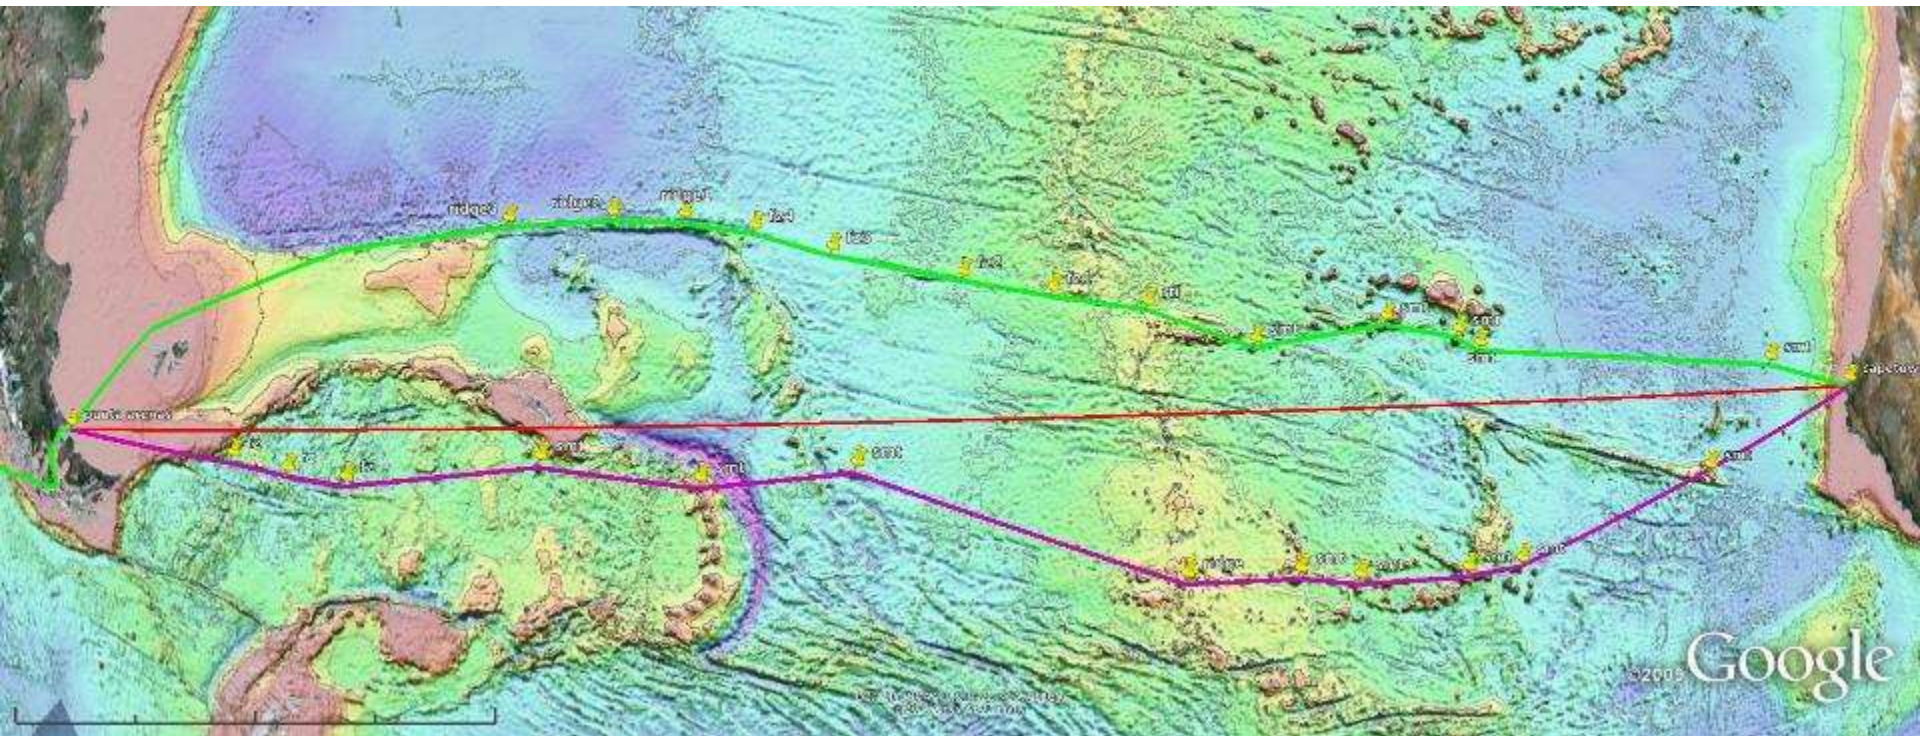

- Declassify US Navy bathymetry data.
- Launch a new satellite altimeter.
- **Improve public archives of bathymetry.
(GEBCO Data Store)**
- **Map the oceans with multibeam
echosounders - ships of opportunity.**

Capetown to Punta Arenas - Melville - Feb, 2011

red - great circle = 6896 km

green - 10 new seamounts = 7130 km (1.034)

violet - 11 new seamounts = 7069 km (1.025)

Capetown to Punta Arenas - Melville - Mar 3, 2011

Conclusions

- Ship soundings are essential for global bathymetry models. Gravity resolution is limited by the ocean depth (~4 km).
- We have assembled 16.5% sonar coverage @ 1 km cells. Smaller cells will have smaller area coverage.
- The “public” contributions are available to everyone without registration/passwords, etc.
- GEBCO could take a leading role this assembly of public data.
- The GEBCO Data Store could also guide ships of opportunity.
